[Title of the Invention] ELECTRICALLY CONDUCTIVE DAMPER
DEVICE FOR SPEAKER

[Scope of Claims for Patent]

1. An electrically conductive damper device for a speaker characterized by comprising a main damper which is formed of damper material having metallic wires attached thereto, and a reinforcing damper which is attached to a part of said main damper on which a voice coil bobbin is mounted.

2. The electrically conductive damper device for the speaker as claimed in claim 1, characterized in that said damper material is formed of a fabric impregnated with thermosetting resin, and said metallic wires are formed of electrically conductive material, said main damper being formed by attaching said metallic wires to said fabric by sewing.

3. The electrically conductive damper device for the speaker as claimed in claim 1, characterized in that said reinforcing damper is attached to such an area of said main damper that a local bending occurring at said mounting part of said voice coil bobbin when said voice coil bobbin is driven by a voice coil may be reduced, whereby said material of said main damper and said metallic wires may be prevented from breaking down.

4. The electrically conductive damper device for the speaker as claimed in claim 1, characterized in that said main

damper and said reinforcing damper are bonded to each other by means of an adhesive.

5. The electrically conductive damper device for the speaker as claimed in claim 4, characterized in that said adhesive has an inner loss to such an extent that sympathetic vibrations of said electrically conductive damper occurring when said voice coil bobbin is driven may be dampened.

6. The electrically conductive damper device for the speaker as claimed in claim 4, characterized in that said main damper and said reinforcing damper are bonded to each other by applying said adhesive.

7. The electrically conductive damper device for the speaker as claimed in claim 4, characterized in that said main damper and said reinforcing damper are bonded to each other by sandwiching said adhesive between them and by fusion bonding.

[Detailed Description of the Invention]

[0001]

[Technical Field to which the Invention Belongs]

The present invention relates to an electrically conductive damper device for a speaker, which can be advantageously used in such a speaker as having a large amplitude.

[0002]

[Prior Art]

In the production of the speaker, an electrically conductive member for inputting voice signals into a voice coil has been integrally attached to a damper in many cases, for the purpose of decreasing number of wiring works. For this purpose, the damper has been composed of damper material such as a fabric or non-woven fabric provided with corrugations, and the electrically conductive member which is formed of braided metallic wires according to a shape of the corrugations and incorporated into the damper material by sewing with fibers such as threads.

[0003]

[Problems that the Invention is to Solve]

However, the above described damper has had poor applicability, because when it has been assembled into the speaker having the large amplitude, a neck portion of the damper and its surrounding area may be locally bent, resulting in break-downs of the damper material and the braided metallic wires.

[0004]

The present invention has been made in view of the above described circumstances, and it is an object of the invention to provide an electrically conductive damper device for a speaker in which an additional reinforcing damper is attached to a main damper in order to reinforce a neck portion of the electrically conductive damper, and these two sheets of dampers

are bonded to each other by means of resin, whereby a local bending is reduced, and break-downs of the damper material and the braided metallic wires can be prevented.

It is also an object of the invention to provide an electrically conductive damper device for a speaker in which properties of the damper can be adjusted by varying an outer diameter of the reinforcing damper or selecting the resin as an adhesive.

[0005]

[Means for Solving the Problems]

In order to solve the above described problems, an electrically conductive damper device for a speaker as claimed in claim 1 is characterized by comprising a main damper which is formed of damper material having metallic wires attached thereto, and a reinforcing damper which is attached to a part of the main damper on which a voice coil bobbin is mounted.

According to the above described structure, an additional sheet of the damper material is attached to the main damper for the purpose of reinforcing a neck portion of the electrically conductive damper, and break-downs of the damper material and the metallic wires incorporated therein can be prevented.

[0006]

The invention as claimed in claim 2 is, in the electrically conductive damper device for the speaker as

claimed in claim 1, characterized in that the damper material is formed of a fabric impregnated with thermosetting resin, and the metallic wires are formed of electrically conductive material, the main damper being formed by attaching the metallic wires to the fabric by sewing.

This will moderate a local bending of the damper, and it will be possible to provide the electrically conductive damper device for the speaker in which break-downs of the damper material and the metallic wires incorporated therein will be prevented.

[0007]

The invention as claimed in claim 3 is, in the electrically conductive damper device for the speaker as claimed in claim 1, characterized in that the reinforcing damper is attached to such an area of the main damper that a local bending occurring at the mounting part of the voice coil bobbin when the voice coil bobbin is driven by a voice coil may be reduced, whereby the material of the main damper and the metallic wires may be prevented from breaking down.

According to this structure, in the area of the main damper provided with the reinforcing damper, a local bending will be reduced. Because the outer peripheral area will be adequately bent on the other hand, the local bending will be moderated, and it will be possible to provide the electrically conductive damper device for the speaker in which the

break-downs of the damper material and the metallic wires which have been incorporated will be prevented.

[0008]

The invention as claimed in claim 4, in the electrically conductive damper device for the speaker as claimed in claim 1, characterized in that the main damper and the reinforcing damper are bonded to each other by means of an adhesive.

By selecting the resin to be employed for bonding, properties of the damper can be adjusted, and it will be possible to provide the electrically conductive damper device for the speaker in which the break-downs of the damper material and the metallic wires which have been incorporated will be prevented.

[0009]

The invention as claimed in claim 5 is, in the electrically conductive damper device for the speaker as claimed in claim 4, characterized in that the adhesive has an inner loss to such an extent that sympathetic vibrations of the electrically conductive damper occurring when the voice coil bobbin is driven may be dampened.

By thus selecting the resin having the large inner loss as the adhesive, an anti-vibration effect of dampening sympathetic vibrations of the damper caused by the metallic wires which have been incorporated can be attained.

[0010]

The invention as claimed in claim 6 is, in the electrically conductive damper device for the speaker as claimed in claim 4, characterized in that the main damper and the reinforcing damper are bonded to each other by applying the adhesive.

By selecting the resin to be employed for bonding, the properties of the damper can be adjusted, and it will be possible to provide the electrically conductive damper device for the speaker in which the break-downs of the damper material and the metallic wires which have been incorporated will be prevented.

[0011]

The invention as claimed in claim 7 is, in the electrically conductive damper device for the speaker as claimed in claim 4, characterized in that the main damper and the reinforcing damper are bonded to each other by sandwiching the adhesive between them and by fusion bonding.

Accordingly, it will be possible to provide the electrically conductive damper device for the speaker in which the break-downs of the damper material and the metallic wires incorporated therein will be prevented.

[0012]

[Preferred Embodiments of the Invention]

Fig. 1 is a sectional view showing a structure of a speaker apparatus in which an electrically conductive damper

device for a speaker according to the present invention is incorporated.

Referring now to Fig. 1, an electrically conductive damper device for a speaker according to the present invention is usually composed of a damper member 14 having a number of corrugations 15 concentrically formed thereon, and another sheet of damper material which is attached to a neck portion of the damper member 14 (near a voice coil bobbin 22) for the purpose of reinforcing the neck portion, and bonded by resin as described below. A specific structure and movements of the damper device while vibrating are illustrated in Figs. 2 and 3.

[0013]

In Fig. 1, numeral 11 generally represents a speaker apparatus, 12 represents a magnetic circuit, 16 represents a yoke, 17 represents a center pole, 18 represents a magnet, 19 represents a top plate, 21 represents a vibration diaphragm, 22 represents a voice coil bobbin, and 13 represents a voice coil. The yoke 16, the center pole 17, the magnet 18 and the top plate 19 constitute the magnetic circuit 12. The voice coil 13 and the vibration diaphragm 21 constitute a vibration system.

[0014]

Fig. 2 is a view cited for reference for explaining a process for producing the electrically conductive damper

device for a speaker according to the present invention.

As shown in Fig. 2, the electrically conductive damper device includes a main damper 141 and a reinforcing damper 142. The main damper 141 includes metallic wires incorporated therein by sewing, and thermosetting resin such as phenol resin or melamine resin which has been applied to or impregnated in the main damper before or after the metallic wires have been incorporated.

The reinforcing damper 142, as well as the main damper 141, has thermosetting resin such as phenol resin or melamine resin applied to or impregnated therein, and is formed into an annular shape by stamping out its inner and outer peripheries.

[0015]

Then, an adhesive is applied to mating faces between the main damper 141 and the reinforcing damper 142, and they are subjected to a heating press and stamped simultaneously into a shape of the damper. Thus, the damper member 14 can be obtained, by bonding the main damper 141 and the reinforcing damper 142 to each other, at the same time with shaping them. It is also possible that instead of applying the adhesive, a coating agent or a laminate film may be sandwiched between the main damper 141 and the reinforcing damper 142.

[0016]

A fabric or non woven fabric such as cotton, aramid fiber

etc. may be employed as material of the main damper 141 and the reinforcing damper 142, to which the thermosetting resin as described above is applied or impregnated. Both ends of a braid of the metallic wires which are incorporated in the damper member 14 to compose the electrically conductive damper are connected respectively to the voice coil 13 and to an exterior input terminal. Audio signals inputted into the exterior terminal are applied to the voice coil 13 through the braid of the metallic wires, and the speaker apparatus as shown in Fig. 1 will be thus actuated.

In the drawings, an area of the main damper 141 overlapped with the reinforcing damper 142 is defined as a range of reinforcement having double sheets.

[0017]

Fig. 3 is a view cited for reference for explaining movements of the electrically conductive damper device for a speaker according to the present invention, while vibrating (upward vibration and downward vibration). For comparison, Fig. 4 shows movements of the conventional damper device.

As described above, the electrically conductive damper device for the speaker according to the present invention consists of the main damper 141, and another sheet of damper material attached to the neck portion of the main damper 141 for the purpose of reinforcement as the reinforcing damper 142. In this embodiment, the two sheets of the damper material are

bonded to each other with various kinds of resin.

[0018]

As apparent from Fig. 3, according to the present invention, in the area of the main damper 141 provided with the reinforcing damper 142, a local bending will be reduced (the bending at the neck portion will be dispersed). Because the outer peripheral area will be adequately bent on the other hand, the local bending will be moderated, and break-downs of the damper material and the metallic wires which have been incorporated will be prevented.

[0019]

Further, by varying an outer diameter of the reinforcing damper, properties of the damper can be adjusted. More specifically, in case where the diameter of the reinforcing damper 142 is made larger, strength of the damper in its entirety will be increased. On the other hand, in case where the diameter of the reinforcing damper 142 is made smaller so as to be attached only to the area near the neck portion, the strength of the main damper 141 around the neck portion can be enhanced, while characteristics of the main damper 141 are maintained.

The latter treatment may be an effective measure, because in modern speakers, the neck portion of the damper is the weakest point in strength and break-downs spreading from the neck portion are prominent. Moreover, in case where advantage

should be taken of the characteristics of only the main damper 141, for example, in a speaker in which a special emphasis is placed on quality of sound, it is possible to restrict the range of reinforcement to a minimum around the neck portion.

[0020]

On the other hand, by selecting the resin to be employed for bonding the reinforcing damper 142 to the main damper 141, properties as the damper can be adjusted. The resin to be employed here includes, for example, polyamide resin, urethane, acryl, NBR (acrylonitril-butadiene rubber), SBR (styrene-butadiene rubber). Particularly, by employing the resin having a large inner loss, an effect for dampening sympathetic vibrations of the damper caused by the incorporated metallic wires can be expected.

[0021]

As described herein above, the present invention can provide an electrically conductive damper device for a speaker in which a local bending is reduced and break-downs of the material of the damper and the metallic wires are prevented, by additionally providing one or more sheets of damper fabric as the reinforcing damper and by bonding it to the main damper by way of various kinds of resin, in order to reinforce the neck portion of the electrically conductive damper. Further, the properties of the damper can be adjusted by varying the outer diameter of the reinforcing damper, or by selecting the

resin to be employed as the adhesive.

[0022]

[Effects of the Invention]

According to the invention as claimed in claim 1, by comprising a main damper which is formed of damper material having metallic wires attached thereto, and a reinforcing damper which is attached to a part of the main damper on which a voice coil bobbin is mounted, an additional sheet of the damper material is attached to the main damper for the purpose of reinforcing a neck portion of the electrically conductive damper, and break-downs of the damper material and the metallic wires incorporated therein can be prevented.

Moreover, because it will be possible to reinforce without employing tough material for the reinforcing damper, the electrically conductive damper device for the speaker can be produced at a low cost.

[0023]

According to the invention as claimed in claim 2, due to the fact that the damper material is formed of a fabric impregnated with thermosetting resin, and the metallic wires are formed of electrically conductive material, the main damper being formed by attaching the metallic wires to the fabric by sewing, a local bending of the damper will be moderated, and it will be possible to provide the electrically conductive damper device for the speaker in which break-downs of the damper

material and the metallic wires incorporated therein will be prevented.

[0024]

According to the invention as claimed in claim 3, due to the fact that the reinforcing damper is attached to such an area of the main damper that a local bending occurring at the mounting part of the voice coil bobbin when the voice coil bobbin is driven by a voice coil may be reduced, whereby the material of the main damper and the metallic wires may be prevented from breaking down, a local bending in the area of the main damper provided with the reinforcing damper will be reduced, and further, because the outer peripheral area will be adequately bent on the other hand, the local bending will be moderated. Therefore, it will be possible to provide the electrically conductive damper device for the speaker in which the break-downs of the damper material and the metallic wires which have been incorporated will be prevented.

[0025]

According to the invention as claimed in claim 4, due to the fact that the main damper and the reinforcing damper are bonded to each other by means of an adhesive, properties of the damper can be adjusted by selecting the resin to be employed for bonding, and it will be possible to provide the electrically conductive damper device for the speaker in which the break-downs of the damper material and the metallic wires

which have been incorporated will be prevented.

[0026]

According to the invention as claimed in claim 5, due to the fact that the adhesive has an inner loss to such an extent that sympathetic vibrations of the electrically conductive damper occurring when the voice coil bobbin is driven may be dampened (selecting the resin having the large inner loss as the adhesive), an anti-vibration effect of dampening sympathetic vibrations of the damper caused by the metallic wires which have been incorporated can be attained.

[0027]

According to the invention as claimed in claim 6, due to the fact that the main damper and the reinforcing damper are bonded to each other by applying the adhesive, the properties of the damper can be adjusted by selecting the resin to be employed for bonding, and it will be possible to provide the electrically conductive damper device for the speaker in which the break-downs of the damper material and the metallic wires which have been incorporated will be prevented.

[0028]

According to the invention as claimed in claim 7, due to the fact that the main damper and the reinforcing damper are bonded to each other by sandwiching the adhesive between them and by fusion bonding, it will be possible to provide the

electrically conductive damper device for the speaker in which the break-downs of the damper material and the metallic wires incorporated therein will be prevented.

[Brief Explanation of the Drawings]

Fig. 1 is a sectional view showing a structure of a speaker apparatus in which an electrically conductive damper device for a speaker according to the present invention is incorporated.

[Name of Document] Abstract

[Abstract]

[Problems]

To provide an electrically conductive damper device for a speaker in which a local bending is reduced, break-downs of damper material and braided metallic wires can be prevented, and at the same time, properties of the damper can be adjusted.

[Means for Solution]

There is provided an electrically conductive damper device for a speaker in which local bending is reduced and break-downs of damper material and metallic wires incorporated in the damper are prevented, by additionally providing one or more sheets of damper fabric as a reinforcing damper 142 and by bonding it to a main damper 141 by way of various kinds of resin, in order to reinforce a neck portion of the main damper 141. Further, properties of the damper can be adjusted by varying an outer diameter of the reinforcing damper 142, or by selecting the resin to be employed as an adhesive.
